## ABSTRACT

We present an  $8\sigma$  detection of cosmic magnification measured by the variation of quasar density due to gravitational lensing by foreground large scale structure. To make this measurement we used 3800 square degrees of photometric observations from the Sloan Digital Sky Survey (SDSS) containing  $\sim 200,000$  quasars and 13 million galaxies. Our measurement of the galaxy-quasar cross-correlation function exhibits the amplitude, angular dependence and change in sign as a function of the slope of the observed quasar number counts that is expected from magnification bias due to weak gravitational lensing. We show that observational uncertainties (stellar contamination, Galactic dust extinction, seeing variations and errors in the photometric redshifts) are well controlled and do not significantly affect the lensing signal. By weighting the quasars with the number count slope, we combine the cross-correlation of quasars for our full magnitude range and detect the lensing signal at  $> 4\sigma$  in all five SDSS filters. Our measurements of cosmic magnification probe scales ranging from  $60 h^{-1}$  kpc to  $10 h^{-1}$  Mpc and are in good agreement with theoretical predictions based on the WMAP concordance cosmology. As with galaxy-galaxy lensing, future measurements of cosmic magnification will provide useful constraints on the galaxy-mass power spectrum.

# Curvature constraints from LSS

# Second Order

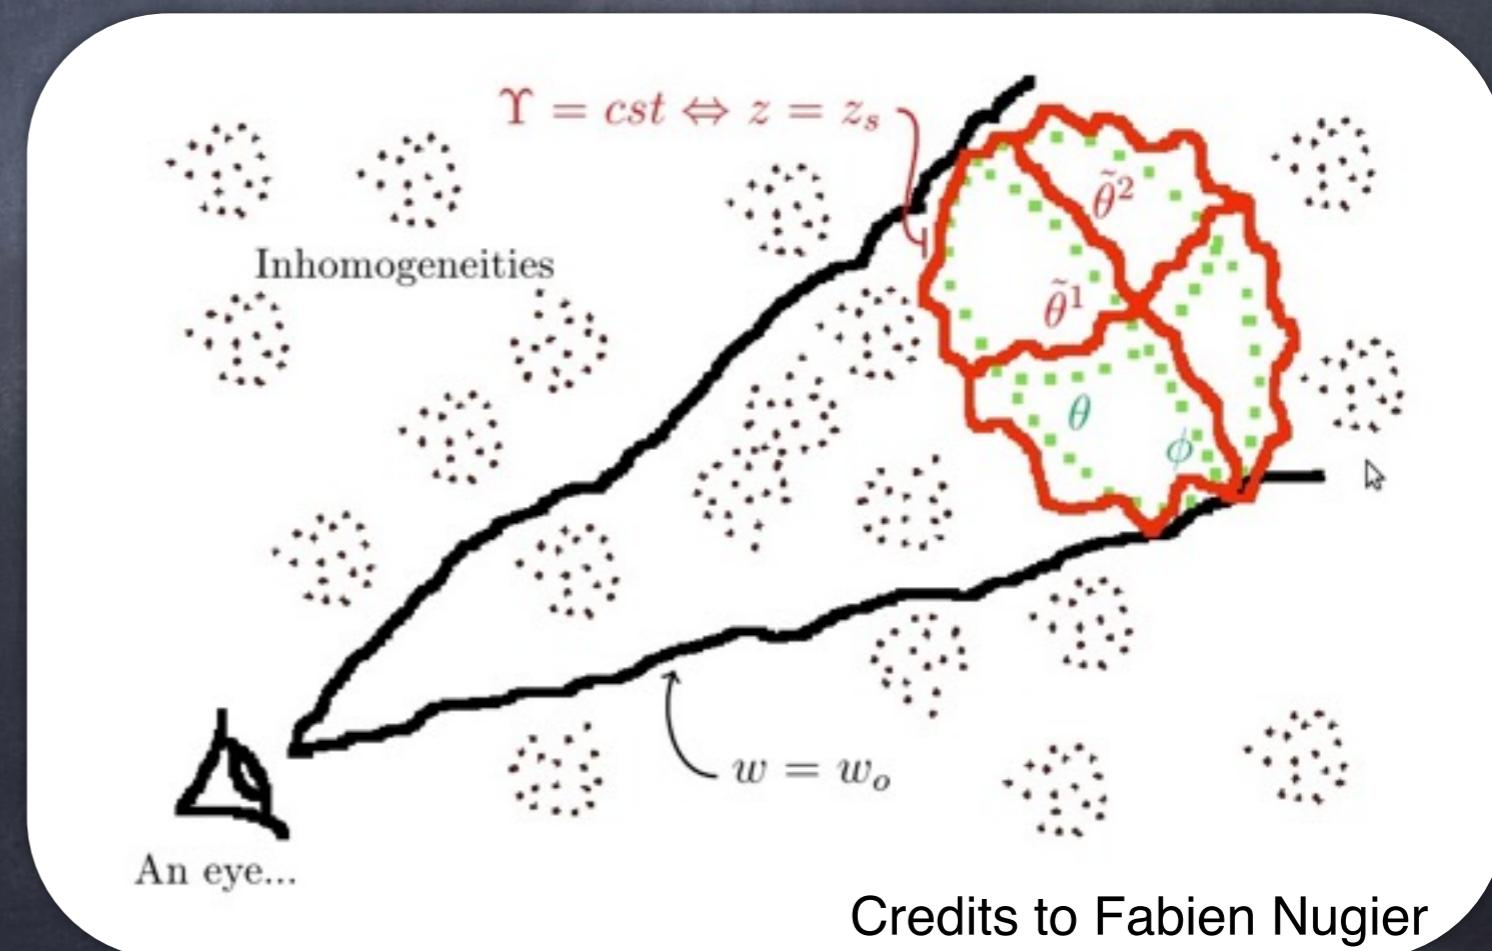

In the weakly non-linear regime second order perturbation theory can be applied

Because of non-linear gravitational effects the power spectrum does not encode all the statistical information.

Born approximation fails  
→ Perturbed geodesics

Geodesic light-cone gauge

# Conclusions

- Relativistic corrections
  - encode useful information
  - may bias the parameter estimation, if neglected
- Multi-tracers technique allows to isolate some relativistic correction. Future surveys should be able to measure them
- relativistic number counts can be generalized to non-flat universes
  - neglecting relativistic effects may bias the curvature parameter as well
- Lensing effects are not negligible on the galaxy bispectrum
- Lensing smoothes the BAO wiggles
